Sunnypilot on Comma 4

This is a design exploration to see how Sunnypilot could work and look on C4 on road.

These designs are made to communicate and get feedback on different ideas and directions. They are not pixel perfect production designs intended to get feedback on details.

Design goals:
Increase the amount of space available in order to accomodate Sunnypilots more feature and stats rich UI compared to Openpilot.

Incorporate navigation (Navigate on Sunnypilot).

Use what's available in stock Openpilot as much as possible to avoid additional work.

I have created two different directions, one with the road video feed and one without.

Direction 1: With video

Active feature indicators and stats can be shown at the top of the screen. Room is of course limited and text needs to be big enough to be easily readable.

Direction 2: Without video

Seeing the video feed of the road with laneline indicators has been very valuable on earlier Comma devices to build an understanding of the system and its capabilites.

Here are some arguments to remove the video feed, caveat is that I haven't used the device yet;

1. On the C4 the screen is so small that it's difficult to see the actual road lanelines, making it harder to assess if the lanelines indicators are correct. This has reduced the utility of the video feed.

2. We get more usable screen real estate. Since there is no clear visual border between OLED display and surrounding glass we can can push UI elements to the edge of the display and it still looks good without margins. The same thing is done on Apple watch.

3. Removing the video stream reduces visual clutter/noise.

There's now more space and easier to see active feature indicators and stats.

Model confidence levels work the same as on Openpilot but moves up and down a bit less to create room for the driver monitor indicator.

Comparison: with and without video
